

Adaptive Methods in Clinical Research

Lecture 3: Multi-Arm Multi-Stage (MAMS) Designs

Pavel Mozgunov

MRC Biostatistics Unit
October-November 2023

Multiple treatments

Treatments T_1, \ldots, T_K are available

One of them is to be selected for further study

- All have passed Phase I
- They are distinct therapies or different doses of the same drug were no dose-response relationship is assumed
- In Phase III the selected treatment will be compared to the control

Naive approach

Conduct separate Phase II trials for each T_k

- sample size will get large
- especially if α is reduced to allow for **multiple comparisons**
- → special methods have been developed

The fixed sample size (single-stage) design

Single stage selection screens

Suppose that responses to T_k are

$$Y_{ki} \sim N(\mu_k, \sigma^2), \ k = 0, 1, \dots, K, i = 1, \dots, n_k$$

 T_0 is the control treatment, there are n_k patients treated on T_k , and the mean of their responses is \bar{y}_k

Put

$$Z_k = \frac{1}{\sigma} \sqrt{\frac{n_0 n_k}{n_0 + n_k}} (\bar{y}_k - \bar{y}_0)$$

then

$$\boldsymbol{Z} \sim N(\boldsymbol{m}, \boldsymbol{V})$$

with

$$m_k = \frac{1}{\sigma} \sqrt{\frac{n_0 n_k}{n_0 + n_k}} (\mu_k - \mu_0); \quad v_{kk'} = \sqrt{\frac{n_k n'_k}{(n_0 + n_k)(n_0 + n'_k)}}, \ k \neq k'; \quad v_{kk} = 1$$

Single stage selection screens

Select treatment T_{k^*} where

$$Z_{k^*} = \max(Z_1, \ldots, Z_K)$$

provided that

$$Z_{k^*} \geq u$$

Otherwise, make no selection

Finding a design

- Put $n_k = r_k n_0$, k = 1, ..., K, for chosen values of $r_1, ..., r_K$
- Often r₁ = ··· = r_K;
 although the common value may be < 1
- Have to find n_0 and $u \Rightarrow$ need 2 equations

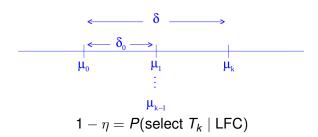

Specifying the accuracy

$$\begin{array}{rcl} \nu &=& P(\text{select a treatment} \mid \mu_0 = \mu_1 = \cdots = \mu_K) \\ 1 - \eta &=& P(\text{select } T_k \mid \mu_k = \mu_0 + \delta \text{ and} \\ && \mu_k = \mu_0 + \delta_0, \ k = 1, \ldots, K-1) \end{array}$$

were $0 \le \delta_0 < \delta$.

Set ν to be small and 1 $-\eta$ to be large

Least favorable configuration LFC

if $\mu_{r+1}, \ldots, \mu_k \ge \mu_0 + \delta$ and $\mu_1, \ldots, \mu_r \le \mu_0 + \delta_0$ then T_{r+1}, \ldots, T_k are good treatments, while the rest is not good enough. If follows that

 $P(\text{select one of } T_{r+1}, \ldots, T_k) \ge 1 - \eta$

Example

$$\sigma = 4.4$$

 $\nu = 0.05, \ 1 - \eta = 0.9$
 $K = 4, \ r_1 = \cdots = r_4 = 1$

δ	δ_{0}	n	n_0
2.5	0.625	375	75
2.0	0.500	585	117
1.5	0.375	1040	208

$$n=(K+1)n_0$$

Comparison

- 4 separate comparative trials;
- $\alpha = 0.05, \ 1 \beta = 0.9 \ \text{and} \ \delta = 2$
- Sample size per trial 204
- Total sample size 816
- Reduce sample size by \approx 30%
- Without adjusting for multiplicity

Two-stage selection process

Two-stage selection screens

Suppose that responses to T_k are $Y_{ki} \sim N(\mu_k, \sigma^2), \ k = 0, 1, ..., K, i = 1, ..., n_k$.

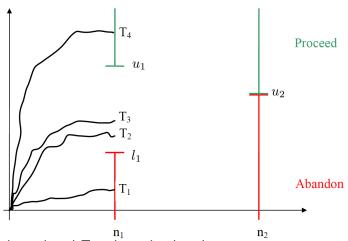

In Stage 1, n_k patients are treated on T_k , with mean response \bar{y}_{1k}

$$Z_{1k} = \frac{1}{\sigma} \sqrt{\frac{n_0 n_k}{n_0 + n_k}} (\bar{y}_{1k} - \bar{y}_{10})$$

After Stage 1, an interim analysis is conducted

- If $Z_{1k} < I_1$, then T_k will be dropped
- If $Z_{1k'} = \max(Z_{11}, \dots, Z_{1K}) > u_1$, then $T_{k'}$ will be selected

Stopping early

Best treatment only

(e.g. Stallard & Todd, 2003; Whitehead & Jaki 2009)

- If no treatment is selected after Stage 1
- and not all are dropped

then n_k further patients are treated on the control and **the best** remaining active treatment, $T_{k'}$.

At the end of Stage 2, the statistic

$$Z_{2k'} = rac{1}{\sigma} \sqrt{rac{2n_0n_{k'}}{n_0 + n_{k'}}} (\bar{y}_{2k'} - \bar{y}_{20})$$

is calculated, where $\bar{y}_{2k'}$ denotes the mean response on $T_{k'}$ over all $n_{k'}$ patients.

If $Z_{2k'} > u_2$, then $T_{k'}$ will be selected.

All promising treatments

(Magirr et al, 2012)

- If no treatment is selected after Stage 1
- and not all are dropped

then n_k further patients are treated on the control and and on each of the remaining active treatments.

At the end of Stage 2, the statistics

$$Z_{2k} = \frac{1}{\sigma} \sqrt{\frac{2n_0n_k}{n_0 + n_k}} (\bar{y}_{2k} - \bar{y}_{20})$$

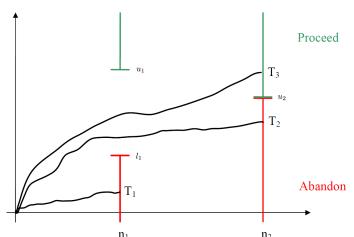

are calculated, where \bar{y}_{2k} denotes the mean response on T_k over all n_k patients.

If $Z_{2k'} = \max(Z_{21}, \dots, Z_{2k}) > u_2$, then $T_{k'}$ will be selected.

All promising treatments

(Magirr et al, 2012)

 T_1 eliminated at interim and T_3 selected at final analysis

Drop the loser

- An alternative is to fix the number of treatments that will be dropped during each stage;
- This is called as the "drop-the-loser" design
- The design controls the FWER and the sample size can be pre-specified in advance;
- However, one has to stick with the pre-specified rules for dropping (even if two treatments perform very similar).

Finding a design

$$\begin{array}{rcl} \nu &=& P(\text{select a treatment} \mid \mu_0 = \mu_1 = \cdots = \mu_K) \\ 1 - \eta &=& P(\text{select } T_k \mid \mu_k = \mu_0 + \delta \text{ and} \\ && \mu_{k'} = \mu_0 + \delta_0, \ k' = 1, \ldots, K - 1) \end{array}$$

as before.

- Fix the sample size ratios $r_k = m_k/m_0 \Rightarrow \text{find } l_1, u_1, u_2, m_0$
- Further constraints can be set, such as
 - (i) $l_1 = 0$, $u_1 = \infty$
 - (ii) $I_1 = -\frac{u_2}{3}, u_1 = \infty$
 - (iii) $I_1 = 0, b = \frac{4}{3}u_2$

and a solution can be computed and evaluated

Example: all promising

$$\begin{split} \sigma &= 4.4, \ \delta = 2, \ \delta_0 = 0.5 \\ \nu &= 0.05, \ 1 - \eta = 0.9 \\ \mathcal{K} &= 4, \ r_1 = \dots = r_4 = 1 \end{split}$$

I_1	u_1	u_2	n_0	n_{max}	$ESS_0(N)$	$ESS_{LFC}(N)$
0	∞	2.15	59	590	460	542
$-\frac{u_{2}}{3}$	∞	2.17	59	590	532	574
0	$\frac{4u_2}{3}$	2.18	61	610	474	460

 n_{max} is the maximum sample size

 $ESS_0(N)$ and $ESS_{LFC}(N)$ are the expected total sample sizes under the null and least favourable configuration, respectively

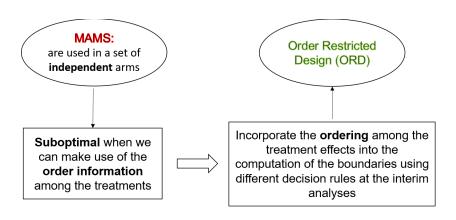

Extensions

- Covariates can be included under orthogonality
 - Orthogonality holds if same number of subjects on each treatment and stage
 - approximately holds for large n
- Non-normal endpoints based on asymptotics

Beyond Independent Treatment Arms

Aim of the study: select all the promising treatment arms.

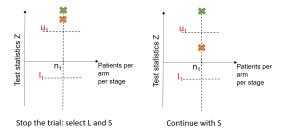

Notations

Let consider a MAMS with:

- three treatment arms: control, treatment L and treatment S
- one interim analysis
- pre-specified allocation of patients
- Z_{1k} the test statistic relative to the arm k at the first stage
- $\theta^{(L)} > \theta^{(S)}$
- $\theta^{(L)}$ and $\theta^{(S)}$ are the effects at the longest and shortest treatment durations, respectively

Decision rules when $\theta^{(L)} \ge \theta^{(S)}$, $Z_{1L} \ge u_1$

Treatments: L and S

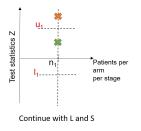

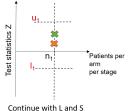

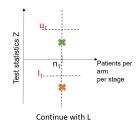

Decision rules when $\theta^{(L)} \ge \theta^{(S)}$, $I_1 < Z_{1L} < u_1$

Treatments: L and S

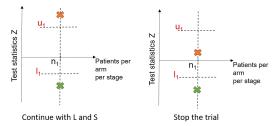

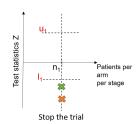

Decision rules when $\theta^{(L)} \ge \theta^{(S)}$, $Z_{1L} \le I_1$

Treatments: L and S

Family-wise Error Rate and Power requirement

Family-wise Error Rate (FWER)

Control of the FWER:

 $P(\text{reject at least one true } H_{0k}, k \in \{L, S\}|\text{null treatment effect}) \leq \nu$

Power requirement

Power the study at $(1-\eta)$ to reject both hypotheses under $\theta=(\theta^{(L)},\theta^{(S)})$, where $\theta^{(L)}\geq\theta^{(S)}\geq\delta_0>0$ and δ_0 the minimum clinically relevant difference.

Simulations

Simulations were run to compare the 3-arm 2-stage Order Restricted Design (ORD) with:

- a) Fixed Sample Design (FSD)
- b) Fixed Sample Design with hierarchical test (FSD(h)): that is the 3-arm 1-stage ORD
- c) modified MAMS design (MAMS(m)): the trial is continued until the decision on each arm has been made

The **measure of performance** is the probability of rejecting both hypotheses.

The **efficiency** of the proposed design is measured by its expected sample size (ESS).

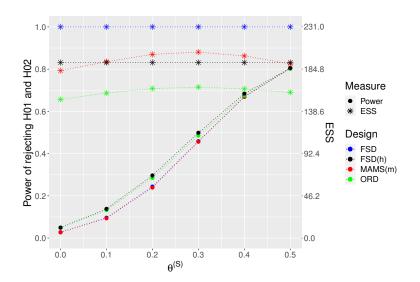

Settings

- The FWER at level $\nu = 0.05$
- all designs are powered at 80% to reject both hypotheses under $\theta = (0.5, 0.5)$
- different scenarios of $\theta = (0.5, \theta^{(S)}), \ \theta^{(L)} \ge \theta^{(S)}$
- use of triangular bounds for the 3-arm 2-stage ORD and MAMS(m) designs

Probability to reject both hypotheses

Discussion

- MAMS trials can provide huge efficacy gains (compared to the several two parallel arm trials) while maintaining type I and type II errors;
- Methods for MAMS are developed developed and recognised by both funders and HAs;
- MAMS designs are implemented in many R-packages including MAMS, rpact, and gsDesign.
